# Outline

- Introduction & Preliminaries
- Problem Definition
- Graph state space
- Iterative multi-source Beam Search
- Experimental Evaluation: General & special problem
- Conclusions

# Introduction

- Objects we deal with: sequences (strings) over finite alphabet  $\Sigma$ 
  - DNA/RNA over {A, T, G, C/U}
  - Proteins over 20 (canonical) amino acids: {A, C, D, E, P, Q...}
- **One of central tasks in computational biology:**
  - sequence comparison, finding common motifs between sequences
  - compare structurally but also semantically/functionality
  - sequence alignment problems
- **Subsequences:** reveal structural similarities → **Longest common subsequence problem** variants (studied 50 years already)

# Longest common subsequence problem (LCSP)

## Definition (LCSP)

**Input:** Given an arbitrary set of sequences  $S = \{s_1, \dots, s_m\}$

**Task:** Find a subsequence  $s$  **common** for all sequences from  $S$  with **maximum possible length** ( $|s|$ ).

## Example

Input:  $S = \{\text{AATTGC, ATTAC}\}$

LCS solution:  $s = \text{ATTC}$

- Basic problem in computational biology, well-solved theoretically and practically

# LCS: Literature & Problem Variants

- When  $m = 2$  – polynomially solvable (in  $O(n^2)$ ): [Dynamic programming](#), Hunt-Szymanski, Hirschenberg, ...
- When  $m$  arbitrary large –  $\mathcal{NP}$ -hard:
  - subject of interest within last 30 years: approximation approaches, meta-heuristics (ACO, [Beam search](#), ...), but also exact approaches (A\*, anytime approaches, DAG-based, ...)

## Problem-related practical variants:

- Arc-annotated LCS problem
- Constrained (restricted/imposed) LCS problem
- Repetition-free, filled, ...
- **Gapped LCS problem**

# The gapped LCS problem

## Definition (A gap sequence)

Given is a sequence  $s$  and an assigned function  $G_s: \{1, \dots, |s|\} \mapsto \mathbb{N}$ . A pair  $(s, G_s)$  is called a **sequence with gaps**.

## Definition (A gapped subsequence)

Sequence  $\tilde{s}$  is a **gapped subsequence** of  $(s, G_s)$  iff

- $\tilde{s}$  is a subsequence of  $s$
- the gap constraint  $G_s$  is fulfilled w.r.t. *positions of appearances* of letters of  $\tilde{s}$  in  $s$ 
  - suppose  $i_1, \dots, i_{|\tilde{s}|}$  are **positions of embedding**  $\tilde{s}$  in  $s$
  - $(\forall j = 2, \dots, |\tilde{s}|) i_j - i_{j-1} \leq G_s(i_j) + 1$

# Problem definition

## Example

$s = \text{AATTGC}$ ,  $G_s(\cdot) = 1$

- $\tilde{s} = \text{ATG}$ , the embedding:  $\text{AATTGC}$  (**valid** gapped subsequence)
- $\tilde{s} = \text{ATG}$ , the embedding:  $\text{AATTGC}$  (**invalid** gapped subsequence)

## Definition (The multiple (variable) gapped LCS problem – MVGLCSP)

**Input:** Given is a set of gapped sequences  $\{(s_1, G_{s_1}), \dots, (s_m, G_{s_m})\}$ .

**Task:** Find the longest subsequence  $\tilde{s}$  so that

- $\tilde{s}$  is common subsequence of each  $s_i$ ;
- $\tilde{s}$  fulfills all gap constraints  $G_{s_i}$  ( $i = 1, \dots, m$ )

**Note:** when  $G_{s_i} = n$  (the length of longest sequence)  $\Rightarrow$  VGLCSP = LCSP.

# Literature & Motivation for VGLCSP

- Peng and Yang (2012, 2014): studied the  $m = 2$  (poly) version by **three dynamic programming** approaches (basic one, two advanced involving complex data-structures to speed up)
- Manea et al. (2024): Complexity bounds, (parameterised) complexity analysis investigated
- **NP-hard** under arbitrary large  $m$

## Motivation:

- **Genetics and molecular biology**: applications in DNA/protein analysis where variable structural distances between residues must be respected
- **Time-series analysis**: in settings where events are required to occur within specified temporal delays (Lainscsek et al. (2015))

# Methodology

- Based on the significant extension of the state space graph formulation for LCS problem (Djukanovic et al. (2020))
- **Gap constraints:** incorporated to cut-off invalid extensions (edges) among the LCS extensions immediately
- **First position to start the search free** — many root/source nodes in the state graph, generally separated subgraphs

## Root-based state graph formulation: rough idea

- Each **state**  $v = (p^L, l^v)$ : one or more feasible partial solutions characterized by
  - a vector of positions  $p^L$  referring to suffixes of input sequences relevant to further expand these sols
  - the length of current partial solution  $l^v$
- **Expansion** of  $v$ : extend partial solutions feasibly by one letter (concatenation) in all possible ways (non-dominantly), respecting gap constraints
- **Non-expandable nodes**: complete solutions; start from  $p^L = 1$  (empty solution), the complete problem

**Decision: selection of (match)  $p^L$  for root node (corr. empty sol.)**

⇒ possibly **(exponentially) many root nodes** (the search start)

Space( $p^L$ ): State (sub) graph induced by node  $(p^L, 0)$ .

# Root-based state graph formulation: example with the match $r = (1, 1)$ (obviously a valid root node)

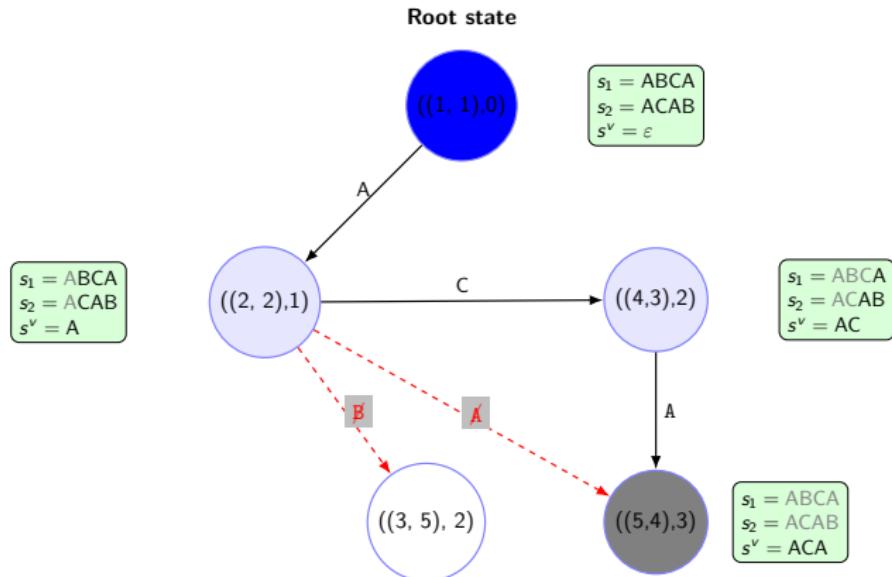

Figure: State space graph  $\text{Space}(r = ((1, 1), 0))$  for MVGLCSP between the sequences  $\boxed{A} \text{BCA}$  and  $\boxed{A} \text{CAB}$ , assuming  $G_1 = G_2 = 1$ .

## An issue with the root-state-space formulation: example

### Example

$S = \{s_1 = \text{ATGG}[\text{A}]AA, s_2 = \text{ATCC}[\text{A}]AA\}$ , with gap constraints  
 $G_{s_1} = G_{s_2} = 1$ . In this instance, any state with position vector  $\mathbf{p}^L = (5, 5)$  cannot be reached from the initial state  $((1, 1), 0)$  by standard direct transitions.

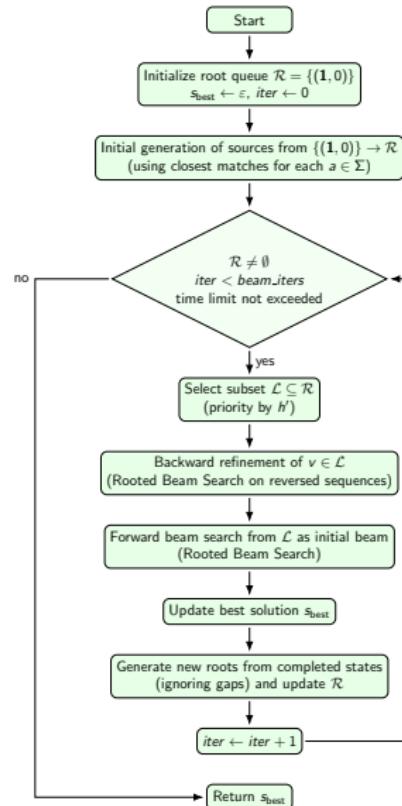

**Consequence:**  $((5, 5), 0) \notin \text{Space}((1, 1)) \Rightarrow$  The optimal common subsequence AAA is unreachable.

- The VGLCSP may exhibit multiple, – potentially exponentially many – disconnected root components

## Iterative multi-source beam search (IMSBS) strategy

- **Full state space** of a VGLCSP instance:  $\bigcup_{v \in \mathcal{R}} \text{Space}(\mathbf{p}^{L,v})$ , with  $v = (\mathbf{p}^{L,v}, 0) \in \mathcal{R}$  all root states
- Explicitly enumerating all root states computationally prohibitive ( $O(n^m)$  time)
- **IMSBS** (rough idea):
  - Based on **beam search** (for exploring  $\text{Space}(r)$ ): limited breadth-first-search (BFS) strategy, parameter  $\beta$  controls the number of nodes to be further pursued
  - Dynamically explore multiple promising regions ( $\text{Space}(r)$ ) of the state space: move from one to another rooted subgraph
  - **Iteratively identify** a set of **promising** candidate root states

# Workflow of the IMSBS

# Heuristic guidances in BS

Three LCS heuristic guidances used:

- “Look-ahead” for the remaining sequence length:  $\text{UB}_1(v)$
- *Character Frequency Alignment* score:  $\text{UB}_2$ 
  - sum up the maximum possible occurrences of each letters in subsequences
- *A probability-based heuristic* guidance:  $h_{prob}$  ( the pre-processed matrices of probabilities (Mousavi and Tabataba (2012)))

## Experimental Evaluation: arbitrary large $m$ -case

- Bs: a baseline beam search approach, allowing only a single iteration of IMSBS (utilizing a huge  $\beta$ )
- IMSBS-GREEDY: a variant of IMSBS with a fixed beam-width parameter  $\beta = 1$  for the forward BS, performing a larger number of beam search (impact of iterations on the overall performance of IMSBS)
- IMSBS: a tuned version; configured to use an average runtime comparable to that of Bs

## Benchmark set RANDOM

For each combination of instance parameters

- $n \in \{50, 100, 200, 500\}$
- $m \in \{2, 3, 5, 10\}$
- $|\Sigma| \in \{2, 4\}$

10 random problem instances are generated (sequences uniformly at random).

The gap constraints generated from  
 $G_s(\cdot) \in \mathcal{U}(\{ \lfloor 0.5 \cdot |\Sigma| \rfloor, \dots, \lfloor 1.5 \cdot |\Sigma| \rfloor \})$ .

⇒ A total of **320 problem instances** is generated.

# Parameter tuning of IMSBS

We fixed (less sensible) params:

- BS (backward):  $\beta' = 10$ , and UB<sub>2</sub> (efficient)
- Candidate root nodes from  $\mathcal{R}$  ordered by UB<sub>2</sub> (decreasingly)
- At each iteration, **10 best nodes** taken from  $\mathcal{R}$  as the initial beam

## Tuned parameters:

- $\beta$  (in BS-forward)
- Heuristic guidance in BS (forward)
  - {UB<sub>1</sub>, UB<sub>2</sub>,  $h_{prob}$ }

## Bs: influence of different $\beta$ and heuristic guidances

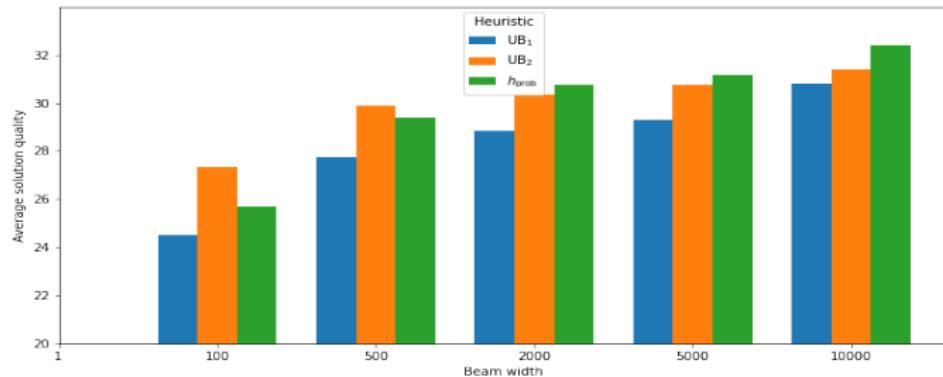

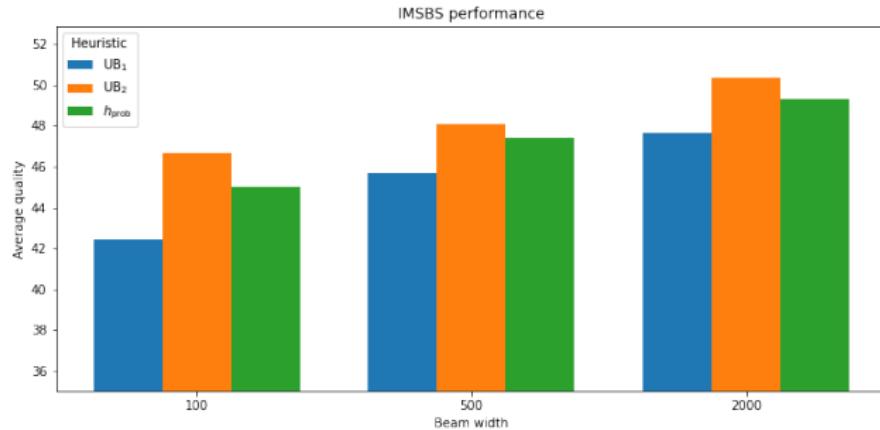

Figure: Avg. quality over all instances from the RANDOM benchmark suite.

(Baseline) Bs  $\implies \beta = 10,000$  and  $h = h_{\text{prob}}$

# Parameter tuning of IMSBS

Avg. quality for different IMSBS settings over all instances from the RANDOM benchmark suite.

IMSBS  $\Rightarrow h = \text{UB}_2$  and  $\beta = 500$ , and  $\text{beam\_iter} = 100$ .

IMSBS-GREEDY:  $\beta = 1$ ,  $\text{beam\_iter} = 10,000$  (comparable/slightly larger avg. runtime to that of IMSBS)

# Numerical results

| Inst.       |          |            | Bs               |                   | IMSBs-GREEDY     |                   | IMSBs            |                   |

## Numerical results for $m = 2$ case

- DP-1: the basic dynamic programming ( $O(n^2m^2)$ )
- DP-2: an advanced dynamic programming, uses Incremental Suffix Maximum Queries (ISMQ) with Col and All matrices for acceleration ( $O(n^2 + mn)$ )
- DP-3: an enhanced dynamic programming that handles ISMQ with a *dequeue* data structure (slightly modified w.r.t. the literature)
- ILP: an integer linear programming, **proposed in this work**, motivated by the ILP model for LCSP with  $m = 2$

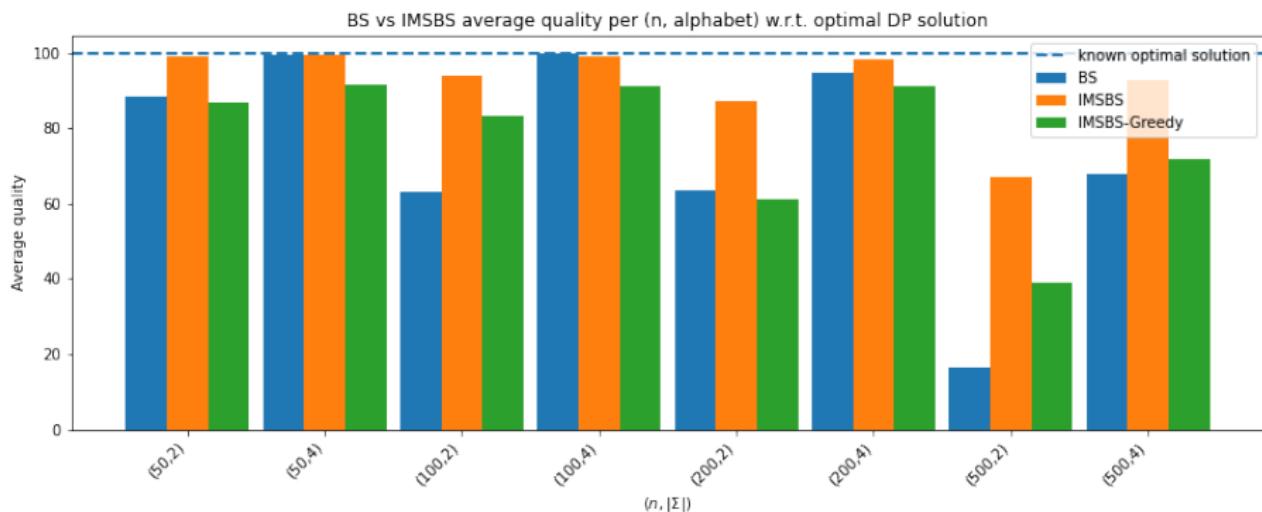

The first known empirical comparison for the  $m = 2$  (80 instances).

# Experimental evaluation

Table: Results on the RANDOM benchmark set for  $m = 2$ : the exact approaches from the literature.

| Inst. |     |            | DP-1             |              | DP-2             |              | DP-3             |              | ILP              |              |
|-------|-----|------------|------------------|--------------|------------------|--------------|------------------|--------------|------------------|--------------|

# The $m = 2$ case: heuristic performance vs. optimal solution

Relative solution quality achieved by the heuristic approaches compared to the optimal solutions.

# Conclusions and Future Work

- Proposed a **general heuristic framework** to solve the multiple VGLCS problem
- IMSBS designed: combines Beam search calls (backward-and-forward manner) in an **iterative way** while producing promising source nodes as candidates for further BS iterations
  - Balancing intensification and diversification
- Empirical studies conducted for the first time on the **synthetic instances**: IMSBS wins over the baseline Beam search

## Future work:

- **Real-world** instance-case scenario
- Lack of more advanced heuristic guidance: **Data-driven/ML heuristic** involving various local and global features (NN-based)

**Thank you for your attention!**
